The 2007 General Assembly unanimously approved legislation to direct VDOT's commissioner to develop, solicit public input on, and publish access management regulations and standards by December 31, 2007 to become effective July 1, 2008. The legislative goals for access management are to:

- Reduce traffic congestion,
- Enhance public safety by decreasing traffic crash rates,
- Support economic development by promoting the efficient movement of people and goods,
- Reduce the need for new highways and road widening by maximizing the performance of the existing state highways, and
- Preserve the public investment in new highways.

To assure that a wide variety of viewpoints were considered, multiple techniques were used to gain public input on the draft regulations and standards including a policy advisory committee with representatives from local government, development, environmental, and transportation engineering organizations. The commissioner approved and published the regulations and standards in December 2007.

Legislation was enacted during the 2008 General Assembly session to require that the regulations and standards be implemented in phases according to highway functional classification. The first phase allowed the access management regulations and standards for VDOT highways classified as principal arterials to take effect July 1, 2008. The design standards are included as Appendix F in the Road Design Manual.

During the second phase, the regulations and standards developed during 2007 for minor arterials, collectors, and local streets underwent an extensive public review in accordance with the Administrative Process Act. These regulations and standards became effective on October 14, 2009.

Appendix G, therefore, contains the standards for the design of intersections, turning lanes, and entrances and for the spacing of entrances, intersections, traffic signals, median openings and crossovers that apply to minor arterials, collectors, and local streets.

NOTE:
1. Maps of state highways by functional classification are on the VDOT web site.
2. The commercial entrance design illustrations at the end of this document replace those in the Minimum Standards of Entrances to State Highways (24 VAC 30-71).
3. The Appendix G standards do not apply to proposed VDOT minor arterials, collectors, and local streets if the construction design plans were presented at a VDOT public hearing prior to October 14, 2009.
4. Web site links are presented within the text in *italics*.

DEFINITIONS

**Acceleration Lane:** An auxiliary lane, including tapered areas, that enables a motorist to increase its speed to a rate that enables it to safely merge with through traffic.

**Access Management:** The systematic control of the location, spacing, design, and operation of entrances, median openings/crossovers, traffic signals, and interchanges for the purpose of providing vehicular access to land development in a manner that preserves the safety and efficiency of the transportation system.

**Arterial:** A major highway intended to serve through traffic where access is carefully controlled, generally highways of regional importance, intended to serve moderate to high volumes of traffic traveling relatively long distances and at higher speeds.

**Auxiliary Lane:** The portion of the roadway adjoining the traveled way for speed change, turning, storage for turning, weaving, truck climbing, and other purposes supplementary to through-traffic movement.

**Channelization:** The separation or regulation of conflicting traffic movements into definite paths of travel by traffic islands or pavement marking to facilitate safe and orderly movements of vehicles, pedestrians and bicyclists.

**Collector:** The functional classification of a highway that provides land access service and traffic circulation within residential, commercial, and industrial areas. The collector system distributes trips from principal and minor arterials through the area to the ultimate destination. Conversely, collectors also collect traffic from local streets in residential neighborhoods and channel it into the arterial system.

**Commercial Entrance:** Any entrance serving land uses other than two or fewer individual private residences. (See “private entrance.”)

**Conflict:** A traffic conflict occurs when the paths of vehicles intersect, an event that causes a driver to take evasive action to avoid collision with another vehicle, usually designated by a braking application or evasive lane change.

**Conflict Point:** An area where intersecting traffic either merges, diverges or crosses. Each conflict point is a potential collision.

**Corner Clearance:** The distance an entrance on a minor side street needs to be separated from the minor side street’s intersection with a major roadway. It is aimed at preventing the location of entrances within the functional area of an intersection.

**Crossover:** an opening in a nontraversable median that provides for crossing movements and left and right turning movements.

**Curb Cut:** An opening along the curb line where vehicles may enter or leave the highway.

**Deceleration Lane:** A speed-change lane including tapered areas that enables a turning vehicle to exit a through lane and slow to a safe speed to complete its turn.
**Design Speed:** The selected speed used to determine the geometric design features of the highway.

**Divided Highway:** A highway on which traffic traveling in opposite directions is physically separated by a median.

**Entrance:** Any driveway, street or other means of providing for the movement of vehicles to or from the state highway system.

**Entrance Throat:** The distance parallel to the centerline of an entrance to the first on-site location at which a driver can make a right turn or a left turn, measured on highways with curb and gutter, from the face of the curb, and on highways without a curb and gutter, from the edge of the shoulder.

**Entrance Width:** The distance edge-to-edge of an entrance measured at the right-of-way line.

**Egress:** The exit of vehicular traffic from a property to a highway.

**Exception:** Permission to depart from standards because of the unique circumstances of the site or project.

**Frontage Road:** A road that generally runs parallel to a highway between the highway right-of-way and the front building setback line of the abutting properties and provides access to the abutting properties for the purpose of reducing the number of entrances to the highway and removing the abutting property traffic from through traffic on the highway.

**Full Access Entrance:** Entrance which allows left-in and left-out movements and right-in and right-out movements.

**Functional Area of an Intersection:** The area beyond the physical intersection that comprises decision and maneuver distance, plus any required vehicle storage length, and is protected through corner clearance standards and connection spacing standards.

**Functional Classification:** The federal system of classifying groups of highways according to the character of service they are intended to provide and classifications made by the Commissioner based on the operational characteristics of a highway. Each highway is assigned a functional classification based on the highway’s intended purpose of providing priority to through traffic movement or adjoining property access. The functional classification system groups highways into three basic categories identified as (1) arterial, with the function to provide through movement of traffic; (2) collector, with the function of supplying a combination of through movement and access to property; and (3) local, with the function of providing access to property.

**Grade Separation:** A crossing of two highways or a highway and a railroad, or a highway and a pedestrian walkway, at different elevations.

**Gradient or Grade:** The rate or percentage change in slope, measured along the centerline of the highway or entrance, either ascending or descending from or along the highway.
**Highway, Street, or Road:** A public right of way for purposes of vehicular travel, including the entire area within the right-of-way.

**Ingress:** The entrance of vehicular traffic into a property from a highway.

**Interchange:** A grade-separated system of access to and from highways that includes directional ramps for access to and from crossroads.

**Intersection:** An at-grade crossing of two or more highways, a crossover, or any at-grade connection with a highway such as a commercial entrance.

**Intersection Sight Distance:** The sight distance required at an intersection to allow the driver of a stopped vehicle a sufficient view of the intersecting highway to decide when to enter, or cross, the intersecting highway.

**Legal Speed Limit:** The speed limit set forth on signs lawfully posted on a highway or in the absence of such signs the speed limit established by Title 46.2, Chapter 8, Article 8 of the Code of Virginia

**Limited Access Highway:** A highway especially designed for through traffic over which abutters have no easement or right of light, air, or access by reason of the fact that their property abuts upon the limited access highway.

**Local Streets/Roads:** The functional classification for highways that comprise all facilities that are not collectors or arterials. Local streets serve primarily to provide direct access to abutting land and to other streets.

**Median:** That portion of a divided highway that separates opposing traffic flows, not including center two-way left-turn lanes, can be traversable or non-traversable.

**Median, Non-traversable (Restrictive Median):** A physical barrier that separates traffic traveling in opposite directions, such as a concrete barrier or landscaped island.

**Median Opening, Directional:** An opening in a restrictive median that physically restricts movements to specific turns such as left turns and U turns.

**Median Opening (Full):** See “Crossover”.

**Median, Traversable (Nonrestrictive Median):** A median that by its design does not physically discourage or prevent vehicles from entering upon or crossing over it, including painted medians.

**Merge:** The process by which two separate traffic streams moving in the same direction combine or unite to form a single stream.

**Minor Arterial:** The functional classification for highways that interconnect with and augment the principal arterial system. Minor arterials distribute traffic to smaller geographic areas providing service between and within communities.
Operating Speed: The speed at which drivers are observed operating their vehicles during free-flow conditions with the 85th percentile of the distribution of observed speeds being the most frequently used measure of the operating speed of a location or geometric feature.

Passing Sight Distance: The length of roadway that the driver of the passing vehicle must be able to see initially, in order to make a passing maneuver safely.

Partial Access Entrance: Entrance with movements limited to right-in or right-out or both, with or without left-in movements.

Peak Hour Volume: The largest number of vehicles passing over a designated section of a street during the busiest 60-minute period within a 24-hour period.

Phase (Signal): That portion of a traffic signal cycle allocated to a specific traffic movement or combination of movements.

Primary Highway: The system of state highways assigned route numbers under 600.

Principal Arterial: The functional classification for a major highway intended to serve through traffic where access is carefully controlled, generally highways of regional importance, with moderate to high volumes of traffic traveling relatively long distances and at higher speeds.

Private Entrance: An entrance that serves up to two private residences and is used for the exclusive benefit of the occupants or an entrance that allows agricultural operations to obtain access to fields or an entrance that allows agricultural operations to obtain access to fields or an entrance to civil and communication infrastructure facilities that generate 10 or fewer trips per day such as cell towers, pump stations, and stormwater management basins.

Ramp Terminal: That portion of a ramp adjacent to the through traveled way, including speed-change lanes, tapers, and islands. Ramp terminals may be the at-grade type, as at the crossroad terminal of diamond or partial cloverleaf interchanges, or the free-flow type where ramp traffic merges with or diverges from high-speed through traffic at flat angles.

Right-of-way: That property within the systems of state highways that is open or may be opened for public travel or use or both in the Commonwealth. This definition includes those public rights-of-way in which the Commonwealth has a prescriptive easement for maintenance and public travel. The property includes the traveled way and associated boundary lines and parking and recreation areas.

Roadway: The portion of a highway, including shoulders, for vehicular use. A divided highway has two or more roadways.

Roundabout: A circular intersection with yield control of all entering traffic, right-of-way assigned to traffic within the circular roadway, and channelized approaches and a central island that deflect entering traffic to the right.

Secondary Highway: The system of state highways assigned route numbers 600 and above.
Shared Entrance: A single entrance to provide access to two or more adjoining parcels.

Shoulder: The portion of the highway that lies between the edge of the traveled way and the break point, excluding turn lanes.

Sight Distance: The distance visible to the driver of a vehicle when the view is unobstructed by traffic.

Sight Triangle: An area of unobstructed sight distance along both approaches of an entrance.

Signal Progression: The progressive movement of traffic, at a planned rate of speed without stopping, through adjacent signalized locations within a traffic control system.

Signal Spacing: The distance between traffic signals along a highway.

Stopping Sight Distance: The distance required by a driver of a vehicle, traveling at a given speed, to bring the vehicle to a stop after an object on the highway becomes visible, including the distance traveled during the driver’s perception and reaction times and the vehicle braking distance.

Storage Length: Lane footage added to a deceleration lane to store the maximum number of vehicles likely to accumulate during a peak period, so as not to interfere with the through-travel lanes.

Taper: The widening of pavement to allow the redirection and transition of vehicles around or into a turn lane; of two types: (a) redirect tapers necessary for the redirection of vehicles along the traveled way; and (b) transition tapers for turn lanes that allow the turning vehicle to transition from or to the traveled way, to or from a turn lane.

Through Movement: The predominant direction of traffic flow through an intersection, straight on most major roads, although the predominant flow of traffic occasionally is in a right or left-turning direction.

Traveled Way: The portion of the highway provided for the movement of vehicles, exclusive of shoulders and turn lanes.

Turn Lane: A separate lane for the purpose of enabling a vehicle that is entering or leaving a highway to increase or decrease its speed to a rate at which it can more safely merge or diverge with through traffic; acceleration and deceleration lanes.

VPH: The number of vehicles per hour, usually referring to vehicles in a peak hour.

Warrant: The criteria by which the need for a safety treatment or highway improvement can be determined.

Weaving: The crossing of two or more traffic streams traveling in the same general direction along a significant length of highway, without the aid of traffic control devices. Weaving areas are formed when a merge area is closely followed by a diverge area, or when an entrance ramp is closely followed by an exit ramp and the two ramps are joined by an auxiliary lane.
SECTION 1- INTRODUCTION

Access Management Concepts

Access management provides a systematic approach to balancing the access and mobility necessities of a roadway. Access management can be defined as the process of managing access to land development, while simultaneously preserving the flow of traffic on the surrounding public road system.

Property owners have a right to reasonable access to the general system of streets and highways. In conjunction, adjacent roadway users have the right to freedom of movement, safety, and efficient expenditure of public funds. Balancing these interests is critical at locations where significant changes to the transportation system and/or surrounding land uses are occurring. The safe and efficient operation of the transportation system calls for effectively managing highway access, via entrances, streets, or other access points.

The specific techniques for managing access involve the application of established traffic engineering and planning principles. Ideally, these principles will:

- Limit the number of traffic conflicts;
- Separate basic conflict areas;
- Separate turning volumes from through movements;
- Provide sufficient spacing between at-grade intersections;
- Maintain progressive speeds along arterials;
- Provide adequate on-site storage lanes.

The application of these principles will minimize disruptions to through traffic caused by entrances and intersections. More specifically, good access management can:

- Reduce crashes and crash potential;
- Preserve roadway capacity and the useful life of roads;
- Decrease travel time and congestion;
- Improve access to properties;
- Coordinate land use and transportation decisions;
- Improve air quality;
- Maintain travel efficiency and related economic prosperity.
Functional Classification

The Federal Highway Administration’s (FHWA) “Functional Classification Guidelines” state that Functional Classification is the process by which streets and highways are grouped according to the character of service they are intended to provide.

Basic to this process is the recognition that individual roads and streets do not serve travel independently in any major way. Rather, most travel involves movement through a network of roads. It becomes necessary then to determine how this travel can be channelized within the network in a logical and efficient manner.

Functional classification defines the nature of this channelization process by defining the part that any particular road should play in serving the flow of trips through a highway network. An illustration of a functionally classified roadway network is presented below.

Since cities and larger towns generate and attract a large proportion of the relatively longer trips, the arterial highways generally provide direct service for such travel. In Rural areas the intermediate functional category, the collectors, serves small towns directly, connects them to the arterial network, and collects traffic from the bottom-level system of local roads, which serves individual farms and other rural land uses.

The same basic concepts apply in urban areas as well. A similar hierarchy of systems can be defined; however, because of the high intensity of land use and travel throughout an urban area, specific travel generation centers are more difficult to identify. In urban areas additional considerations, such as spacing, become more important in defining a logical and efficient network.

Allied to the idea of traffic channelization is the dual role the highway network plays in providing (1) access to property, and (2) travel mobility. Access is a fixed requirement, necessary at both ends of any trip. Mobility, along the path of such trips, can be provided at varying levels, usually referred to as "level of service." It can incorporate a wide range of elements (e.g., riding comfort and freedom from speed changes) but the most basic is operating speed or trip travel time.

Functional Classification of State Highways

Information on the process for establishing a functional classification for a new road or for changing the functional classification for an existing highway is available on the VDOT web site at Functional Classification. Maps identifying the functional classification of all state highways are also presented on this web site.
Schematic of a Functionally Classified Roadway Network

FIGURE 1-1
Relationship of Functionally Classified Systems in Serving Traffic Mobility and Land Access

It was pointed out in the discussion above that the concept of traffic channelization leads logically not only to a functional hierarchy of systems, but also to a parallel hierarchy of relative travel distances served by those systems. This hierarchy of travel distances can be related logically to a desirable functional specialization in meeting the access and mobility requirements. Local facilities emphasize the land access function. Arterials emphasize a high level of mobility for through movement. Collectors offer a compromise between both functions. This is illustrated conceptually above.

Functional classification can be applied in planning highway system development, determining the jurisdictional responsibility for particular systems, and in fiscal planning. These applications of functional classification are discussed in "A Guide for Functional Highway Classification."
Urban and Rural Area Definitions

Urban and rural areas have fundamentally different characteristics as to density and types of land use, density of street and highway networks, nature of travel patterns, and the way in which all these elements are related in the definitions of highway function.

Experience has shown that extensions of rural arterial and collector routes provide an adequate arterial street network in places of less than 5,000 population. Hence urban classifications as discussed herein are considered in the context of places of 5,000 population or more.

Urban areas are defined in Federal-aid highway law (Section 101 of Title 23, U.S. Code) as follows:

"The term 'urban area' means an urbanized area or, in the case of an urbanized area encompassing more than one State, that part of the urbanized area in each such State, or an urban place as designated by the Bureau of the Census having a population of five thousand or more and not within any urbanized area, within boundaries to be fixed by responsible State and local officials in cooperation with each other, subject to approval by the Secretary. Such boundaries shall, as a minimum, encompass the entire urban place designated by the Bureau of the Census."

“Urban area” includes urbanized areas (population of 50,000 and over and urban places (population of 5,000 or more and not located within and urbanized area). For clarity and simplicity, the FHWA uses the term “small urban area” as a substitute for “urban place”.

Rural areas comprise the areas outside the boundaries of small urban areas and urbanized areas.
Functional System Characteristics

Roadway design practices are inextricably linked to the purpose of the road as defined by the functional classification system as follows:

<table>
<thead>
<tr>
<th>CLASSIFICATION</th>
<th>LOCATION</th>
<th>CHARACTERISTICS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Principal Arterial</td>
<td>Rural</td>
<td>Trip lengths for statewide or interstate travel. Integrated movement generally without stub connections. Accommodates movement between (virtually) all areas with pop. 50,000. Two design types: freeways and other principal arterials.</td>
</tr>
<tr>
<td></td>
<td>Urban</td>
<td>Serves major centers of activity with the highest traffic volumes and longest trip lengths. Integrated internally and between major rural connections. Service to abutting lands is subordinate to travel service to major traffic movements. Design types are interstate, other freeways and other principal arterials.</td>
</tr>
<tr>
<td>Minor Arterial</td>
<td>Rural</td>
<td>Links cities, large towns and other traffic generators attracting traffic over long distances. Intercounty service. Designs should be expected to provide for relatively high speeds and minimum interference to through movements.</td>
</tr>
<tr>
<td></td>
<td>Urban</td>
<td>Trips of moderate length at a lower level of mobility than principal arterials. Some emphasis on land access. May carry local bus routes and provide intracommunity continuity but does not penetrate neighborhoods.</td>
</tr>
<tr>
<td>Collector</td>
<td>Rural</td>
<td>Serve intracounty travel with travel distances shorter than on arterial system. More moderate speeds. Divided into major and minor system.</td>
</tr>
<tr>
<td></td>
<td>Urban</td>
<td>Provides both land access and traffic circulation within all areas. Penetrates neighborhoods and communities collecting and distributing traffic between neighborhoods and the arterial streets.</td>
</tr>
<tr>
<td>Local</td>
<td>Rural</td>
<td>Local roads primarily provide access to adjacent land and the collector network. Travel is over short distances.</td>
</tr>
<tr>
<td></td>
<td>Urban</td>
<td>Primarily permits direct land access and connections to other streets. Lowest level of mobility. Long distance through traffic is usually discouraged.</td>
</tr>
</tbody>
</table>

FIGURE 1-2 FUNCTIONAL SYSTEM CHARACTERISTICS

Source: Transportation Research Board (TRB) Circular E-C019, Dated December, 2000
SECTION 2 – INTERSECTION DESIGN; SPACING STANDARDS

Intersection Design Objectives

Intersection design, including entrances, must consider the following items:

- Total approach traffic, design hourly volumes, and turning volumes.
- Composition of traffic (percent of passenger cars, buses, trucks, etc.)
- Operating speed of vehicles
- Functional Classification of Highways
- Adjacent land use
- Physical and Environmental Characteristics
- Pedestrian and Bicycle Accommodation

Major objectives of traffic design concern safety, operational efficiency and driver expectation through consideration of the following:

- The design should fit the natural transitional paths and operating characteristics of drivers and vehicles. Smooth transitions should be provided for changes in direction.
- Grades at intersections should be as nearly level as possible.
- Sight distances must be sufficient to enable drivers to prepare for and avoid potential conflicts.
- On major roadways, intersections must be evenly spaced to enhance the synchronization of signals, increase driver comfort, improve traffic operation, and reduce fuel consumption and vehicle emissions.
Intersection Design Principles

<table>
<thead>
<tr>
<th>Intersection Design Principles</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Limit Number of Conflict Points</td>
</tr>
<tr>
<td>• Coordinate Design and Traffic Control</td>
</tr>
<tr>
<td>• Avoid Complex Maneuvers</td>
</tr>
<tr>
<td>• Separate Conflict Points</td>
</tr>
<tr>
<td>• Favor Major Flows</td>
</tr>
<tr>
<td>• Segregate Movements</td>
</tr>
<tr>
<td>• Accommodate Pedestrians and Bicyclists</td>
</tr>
<tr>
<td>• Consider the Design Vehicle</td>
</tr>
<tr>
<td>• Consider a roundabout</td>
</tr>
</tbody>
</table>

Intersection design principles are as follows:

- Limit the number of conflict points. The number of conflict points among vehicular movements increases significantly as the number of intersection legs increase. For example, an intersection with four two-way legs has 32 total conflict points, but an intersection with six two-way legs has 172 conflict points. Intersections with more than four two-way legs should be avoided wherever possible.

**Figure 2-1 Conflict Points**

Coordinate design and traffic control. Maneuvers at intersections accomplished at low relative speeds require a minimum of traffic control devices. Maneuvers accomplished at high relative speeds are undesirable unless traffic controls such as stop signs or traffic signals are provided. Designs should separate vehicles making conflicting movements. Intersection design should be accomplished simultaneously with the development of traffic control plans.

Avoid multiple and compound merging or diverging movements. These require complex driver decisions and create additional conflicts.

Separate conflict points. Intersection hazards and delays are increased when intersection maneuver areas are too close together or when they overlap. Conflicts should be separated to provide drivers with sufficient time (and distance) between successive maneuvers for them to cope with the traffic conflicts one at a time.

Favor the heaviest and fastest flows. The heaviest volume and higher speed flows should be given preference in intersection design to minimize hazard and delay.

Minimize the area of the conflict. Excessive intersection area causes driver confusion and inefficient operations. Large areas are inherent with long curb return radii and in skewed and multiple-approach intersections. Channelization should be employed to limit the intersection and to guide drivers.

Segregate movements. Separate lanes should be provided at intersections when there are appreciable volumes of traffic traveling at different speeds. Separate turning lanes should be provided for left and right turning vehicles. Left turns necessitate direct crossings of opposing vehicle paths and are usually made at speeds of 10 mph or less for reasons of safety and economy.

Right turns are also usually made at minimum speeds. However, right turns do not involve potential conflicts of such severity as left turns, and are more suited to individual treatment because they take place at the outside of the intersection area. Therefore, right turns may be designed for higher than minimum speeds where adequate right-of-way is available for wider turns.

Accommodate the needs of pedestrians and bicyclists. For example, when pedestrians must cross wide streets, refuge islands are important for pedestrian safety. See Figures 2-11, 3-22 and 3-25 for illustrations. The VDOT web page Bicycling and Walking in Virginia provides information on VDOT policies for accommodating pedestrians and bicyclists on state highways.

A detailed discussion on adapting highways for pedestrians and bicyclists is presented later in this section.
Consider the design vehicle. The shapes and dimensions of turning paths vary for different turning speeds, different angles of turn, and different types and sizes of vehicles. The design vehicle must be identified and turning templates properly applied. See Table 4-1 for Design Vehicle Chart.

Consider a roundabout design. Roundabouts offer an attractive design alternative to conventional intersections. Roundabouts are circular intersections with specific design and traffic control features that convert all vehicular movements to right turns and force traffic to enter and circulate at lower, more consistent speeds. The safety benefits of low vehicle speeds include less severe and less frequent crashes. See the Roundabouts section on page 36 for additional information on the use of, and VDOT’s efforts to promote, roundabouts.

At-grade intersections must provide adequately for anticipated turning and crossing movements. AASHTO’s A Policy on Geometric Design of Highways and Streets, “Intersections” should be reviewed for additional information to be considered in the design since the site conditions, alignment, sight distance, the need for turning lanes and other factors enter into the type of intersection design which would satisfy the design hour volume of traffic, the character or composition of traffic, and the design speed.

A Highway Capacity Manual (HCM) capacity or other appropriate analysis (Corsim/Synchro) should be performed for intersection capacity and signalization requirements, and include a queuing analysis.

Sufficient offset dimensions, pavement widths, pluses, and radii shall be shown in the plans by the designer to insure that sign islands are properly positioned. Care should be taken in the design of four-lane roadways with intersecting two-lane roadways.

If traffic conditions clearly warrant a four-lane divided design for the two–lane road at the intersection, the divided design must be constructed for a sufficient distance to allow for the approaching divided design and the subsequent stop condition ahead to be properly signed. The four-lane divided design should not be constructed unless it is clearly warranted and the approaches can be properly signed or the minor road is expected to be improved to a divided status in the near future.
Examples of typical geometric design applications are presented below and on the following three pages. Note: These examples are not all-inclusive. Other options maybe developed, which would require VDOT approval.

FIGURE 2-2 INGRESS / EGRESS LANE AND CROSS PARCEL CONNECTION ILLUSTRATION

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”
FIGURE 2-3 TYPES OF ACCESS CHANNELIZATION

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.
Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.

FIGURE 2-4 TYPES OF ACCESS CHANNELIZATION
Minimum Angle of Intersections

Streets should intersect at right angles; however, intersecting angles between 60 and 90 degrees are allowed.
Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board's “Policy for Integrating Bicycle and Pedestrian Accommodations”.

FIGURE 2-8 ILLUSTRATION OF ENTRANCE AND INTERSECTION SPACING
Signalized Intersection Spacing

One of the variables involved in the planning, design and operation of signalized arterial streets is “Signalized Intersection Spacing” (See Table 2-2). Efficient traffic progression is essential on arterials in order to maximize safety and capacity. Moreover, at high progression efficiencies, fewer vehicles are required to come to a stop. Deceleration noise is reduced: thus, vehicle emissions, fuel consumption and delay are minimized. Since capacity will always be an issue on an urban arterial once urban development has occurred, the signal spacing must be such that very high progression efficiencies can be obtained over a wide range of through and turn volumes which change over time and which differ by time of day.

Selecting long and uniform signalized intersection spacing is an essential element in establishing spacing standards. Several studies have found that the number of crashes and crash rates increases with the frequency of traffic signals. For example an increase in signal density from 2.0 or less to 2.1 to 4.0 signals per mile can result in a 70% increase in the average crash rate – from about 2.8 to 4.8 crashes per million vehicle miles. The increased number of signals per mile also results in poor fuel efficiency and excessive vehicle emissions.

Arterials are intended to provide a high degree of mobility and serve the longer trips. Since movement, not access, is the principal function, access management is essential in order to preserve capacity and safety. [AASHTO’s “A Policy on the Geometric Design of Highways and Streets” (Green Book)]. Further, the adoption of functional design, in lieu of volume based design, represents a major change in the philosophy of planning and design of street and highway systems.

A uniform signal spacing of ½ mile provides for efficient signal progression at speeds of 30 mph to 60 mph along arterials. At these speeds maximum flow rates are achieved and fuel consumption and emissions are kept to a minimum.
Generally a ½ -mile spacing will enable traffic flow at a wide range of speeds with cycle lengths ranging from 60 to 120 seconds. A ½-mile spacing is needed to provide efficient progressions at 30 mph with a 120-second cycle commonly used in developed urban areas during peak hours. At slower speeds the increase in headway will result in a serious reduction in flow rate. (Source: TRB Access Management Manual. 2003)

**TABLE 2-1 RELATIONSHIP BETWEEN SPEED, CYCLE LENGTH, AND SIGNAL SPACING**

**General Intersection and Entrance Spacing Criteria**

1. Functional classification of highway
   - Purpose of the highway for mobility vs. access to property

2. Highway speed limit
   - The higher the speed, the longer the distance to safely decelerate for turning movements

3. Traffic signal
   - Separation of signals for efficient traffic progression

4. Type of entrance or intersection
   - As the potential number of turning movements increases, so do the conflict points, leading to a greater potential for traffic crashes, particularly for left turns into and out of entrances or at intersections

5. Rural vs. urban areas
   - Rural: Greater spacing due to lower density, larger parcel size, and higher speed limits. Distances between destinations are longer requiring greater mobility.
   - Urban: Shorter spacing due to higher land use density, smaller parcels with less road frontage, slower traffic speeds, and greater need to accommodate pedestrians/bicyclists. Distances between destinations tend to be shorter so a lower level of mobility may be acceptable.

Other criteria that may need to be considered for new crossover spacing is presented on later in this section.

</tbody>
</table>

**Notes:**

A. Spacing distances apply to both divided and undivided highways unless specified.

B. A proposed intersection that will require a new or closing an existing crossover on a divided highway must also be approved in accordance with the Crossover Location Approval Process Section.

C. Signalized intersection spacing applies to other signals. The unsignalized intersection spacing is the minimum distance between such intersections and between unsignalized and signalized intersections. The partial entrance spacing separates such entrances from each other and from intersections.

D. Roundabouts are separated from other intersections by the unsignalized intersection spacing standard; from other roundabouts by the partial entrance spacing standard.

E. For all commercial entrances, intersections and crossovers, the appropriate intersection sight distance from Table 2-7 must be met; however the intersection sight distance does not control the access spacing shown above.

F. The regulatory exceptions to the spacing standards are presented later in this section.
Footnotes to Table 2-2

1 **Legal Speed Limit** – Use legal speed limit unless the design speed is available and approved for use by VDOT.

2 **Signalized Intersection/Crossover Spacing** – Minor arterial and divided collector spacing is allocated in fractions of a mile: (1/2 mile, 2,640 ft); (1/3 mile, 1,760 ft); (1/4 mile, 1,320 ft); (1/5 mile, 1,050 ft); (1/6 mile, 880 ft); (1/8 mile, 660 ft). It is based on (i) the Signalized Intersection Spacing section and Table 2-1 and (ii) *Transportation and Land Development* by Vergil Stover and Frank Koepke, Institute of Transportation Engineers: “Traffic signal control applied in a sequential pattern according to specific spacing criteria optimize traffic efficiency” … “to reduce fuel consumption, reduce delay, reduce vehicular emissions and improve safety.” Undivided collector spacing is based on stopping sight distance to assure motorists have sufficient distance to see/react to a vehicle exiting an entrance or to a vehicle slowing down to turn into an entrance and stop in time to avoid a collision.

3 **Unsignalized Intersection/Crossover and Full Access Entrance Spacing** – These operate in a similar manner so the spacing standards can apply to these intersections/entrances equally. Minor arterial and divided collector spacing is allocated in fractions of a mile (see Footnote 2) or the length of a right auxiliary turn lane needed for a safe deceleration to turn into an entrance from *Geometric Design of Highways and Streets 2004*, AASHTO, pages 713 to 716. Undivided collector spacing is based on stopping sight distance (see Footnote 2).

4 **Partial Access One or Two Way Entrance Spacing** – Left turn movements are limited (right in/right out with or without left in movement). Spacing is based on sufficient stopping sight distance for motorists to be able to see/react to a vehicle slowing down to turn into an entrance or a vehicle exiting an entrance and stop in time to avoid a collision.

5 **Urban Minor Arterials and Collectors** – “Urban” is an abbreviation of “urban area” as defined in the Introduction to this document.

6 **Rural Minor Arterials and Collectors** – “Rural” is an abbreviation for “rural area” as defined in the Introduction to this document. Rural minor arterial and collector spacing standards are greater than their urban counterparts. Rural areas generally have lower land use density, larger parcel sizes, and higher speed limits. Distances between destinations are longer requiring greater mobility.

7 **Divided and Undivided Collectors** – Spacing between intersections is greater on median divided multi-lane collectors because they carry higher traffic volumes, offer opportunities for greater mobility, and as a result are more likely to evolve to minor arterial status.

8 **Local Street Spacing** – For commercial entrances on local streets (not individual private entrance driveways to homes), a spacing distance of 50 ft between entrance radii is specified to assure a minimum separation between such entrances (illustrated in Figure 4-1).

9 **Corner Clearance** – Corner clearance is the minimum distance entrances on a minor side street need to be separated from an intersection to prevent queued vehicles from backing up into the highway or blocking entrances near the intersection. This separation protects the functional area of the intersection. The greater of the Table 2-2 spacing standards and the corner clearance standard will apply. See the Corner Clearance section for more information.
Spacing Standards for Commercial Entrances/Intersections Near Interchange Ramps

The spacing standards near interchange ramps focus on safe ramp exit and entry movements. Greater separation between ramp terminals and entrances and intersections is necessary for multilane versus two-lane highways because the motorist’s maneuvers at multilane roads are more complex, such as crossing through lanes to reach a left turn lane at an intersection. Functional classification is not applied because arterials may be two lane or multilane. Note: If the off and/or on ramp has a full auxiliary lane, the spacing would be determined as if there were a ramp taper.

Z: Distance between the last access connection and the start of the taper for the on-ramp.
Crossover Location Approval Process

Overview
Tables 2-2 through 2-7 show the minimum crossover spacing and sight distance requirements to be applied on all divided highways without full control of access. Crossovers not meeting these minimums will only be allowed after an individual traffic safety and operational study and approval as outlined below.

The following are some factors, but not all inclusive, that should be considered in the study, if applicable: Operating speed, volume of traffic for crossover and through routes, signal operation/progressions, accidents with and without additional crossover, number of U-turns, weaving maneuvers, alternative solution, capacity analysis, type of vehicles such as school buses, trucks, etc.

Intersection sight distance determinations apply both horizontally and vertically, measured in each direction, and are to be based on a height of driver’s eye of 3.5’ and a height of object 3.5’.

Highway Construction Project
As part of a highway construction project, crossover spacing less than shown as minimum in Table 2-2, will be considered when required by existing intersecting public highways or streets with a current ADT of 100 or greater. All plans at the public hearing stage are to show only those crossovers at public highways and streets which meet these criteria or at other locations that preliminary planning and traffic studies have warranted. The determination of additional crossovers shall be the result of field inspection recommendations of the District Administrator, the State Traffic Engineer, (or other appropriate Engineer) and the State Location and Design Engineer.

The approval of the crossovers shall be the responsibility of the State Traffic Engineer and the State Location and Design Engineer, with the final responsibility for the location of crossover layout on plans resting with the State Location and Design Engineer. Plans at right-of-way stage are to indicate the crossovers as determined and approved by the above criteria. Any plans that are revised during construction for the addition or deletion of crossovers shall be approved as indicated above.

Private Sector Crossover Requests
For non-VDOT project related crossover requests, traffic studies as outlined above must accompany the request for a crossover location that does not meet the minimum spacing standards as shown in Table 2-2. The approval of the addition or deletion of crossovers on an existing VDOT highway shall be the responsibility of the State Traffic Engineer (or other appropriate Engineer) with the concurrence of the State Location and Design Engineer. It shall be the responsibility of the State Traffic Engineer to coordinate such changes with the State Location and Design Engineer in order that these revisions of crossovers may be properly recorded on the original plans.
Exceptions to the Spacing Standards

The Access Management Regulations: Minor Arterials, Collectors, and Local Streets (24VAC30-73-120) identify potential exceptions to the spacing standards for commercial entrances, intersections, and crossovers, Tables 2-2 through 2-4. The Regulations specify the documentation required for approval of exception requests. The exception request is submitted to the District Administrator’s designee. If the exception involves the addition or closing of a crossover, refer to the Crossover Location Approval Process.

The appropriate intersection sight distance from Table 2-7 must be met for all commercial entrances, intersections, and crossovers. If sight distance can not be met, a request for an exception to the sight distance also must be submitted. Section 24VAC30-73-50 B in the Regulations provides details on the sight distance exception process.

Exceptions referenced in section 24VAC30-73-120 of the Regulations to the Tables 2-2 to 2-7 spacing standards include the following:

- The specific location of an entrance is shown on a plan of development or described in a condition proffered as part of a rezoning approved by the locality prior to October 14, 2009 or shown on a site plan, preliminary or final subdivision plat approved by VDOT or the locality prior to October 14, 2009. 24VAC30-73-120 C 3.a.

- The location of the entrance or intersection will meet spacing standards in a VDOT and locality approved access management highway corridor plan that differs from those in Table 2-2. 24VAC30-73-120 C 3.b.

- The proposed entrance or intersection will be located on an older, established urban business corridor where existing entrances and intersections did not meet the spacing standards prior to October 14, 2009. 24VAC30-73-120 C 3.c.

- The proposed public street intersection will be located within a new urbanism, traditional neighborhood type development. 24VAC30-73-120 C 3.d.

- Where a development’s second or additional entrances are necessary for the streets in the development to be eligible for acceptance into the secondary system of state highways in accordance with the Secondary Street Acceptance Requirements (24VAC30-92). 24VAC30-73-120 C 3.e.

- The entrance will be restricted to right-in/right-out movements because there is insufficient usable property frontage on the highway due to parcel dimensions or physical constraints to meeting the spacing standards. 24VAC30-73-120 C 3.f.

- Limiting a proposed signalized entrance to right-in/right-out movements if the proposed entrance does not meet the signalized intersection spacing standards. 24VAC30-73-120 C 5.

For more details on the above exceptions, refer to the Access Management Regulations on the VDOT web site at http://www.virginiadot.org/projects/accessmgt/default.asp.
## Stopping Sight Distance

Stopping sight distances exceeding those shown in the table below should be used as basis for design wherever practical.

In computing and measuring stopping sight distances, the height of the driver’s eye is estimated to be 3.5 feet and the height of the object to be seen by the driver is 2 feet, equivalent to the taillight height of a passenger car. The "K Values" shown are a coefficient by which the algebraic difference in grade may be multiplied to determine the length in feet of the vertical curve that will provide minimum sight distance.

For the minimum lengths of vertical curves for the recommended stopping sight distance for each design speed, and corresponding “K” values, see the AASHTO “Green Book”.

### TABLE 2-5 STOPPING SIGHT DISTANCE

When a highway is on a grade, the sight distances in the table below should be used.

**TABLE 2-7 INTERSECTION SIGHT DISTANCE**

Source: AASHTO Green Book (See next page for more detail)

**For all tables, use design speed if available, if not use legal speed.**

The term "Major Road" refers to the road with the higher functional classification, or if both have the same classification, the road with the higher volume.
Intersection sight distance does not control the access spacing for entrances and intersections shown in Table 2-2.

For major roadways of more than four lanes, large truck volumes on a minor road or crossover, or median widths over 60’, see AASHTO’s A Policy on Geometric Design of Highways and Streets.

The designer must check each intersection to insure that these values are obtained. On a typical two-lane road horizontal curve there are numerous objects that restrict sight distance such as cut slopes, buildings, vegetation, vehicles, etc.

These obstructions should be considered when reviewing commercial entrances. A divided highway can have similar problems. It is very important to obtain adequate commercial entrance sight distance from the entrance as well as the left turn position into the entrance. A design exception must be granted by the State Location and Design Engineer (or designee), and if applicable, the Federal Highway Administration for deviating from required sight distance standards.

Intersection Sight Distance values in the table above permit a vehicle stopped on minor road or crossover, to cross the major road safely or merge safely in the case of turns.

The Intersection Sight Distance table above is based on the following criteria:

The AASHTO Green Book shows that it requires 7.5 seconds for a passenger car to turn left onto a two-lane road. For each additional lane to be crossed – add 0.5 seconds. Therefore:

<table>
<thead>
<tr>
<th>2 Lane Major Road (crossing one lane)</th>
<th>Taken directly from 2004 AASHTO, Exhibit 9-55, Page 661 (stopped car crossing one lane and turning left onto a highway with no median) 1.47 X (speed) X 7.5 (per pg. 660) = SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 Lane Major Road (crossing two lanes)</td>
<td>Taken directly from 2004 AASHTO, Exhibit 9-64, Page 672 (stopped car crossing two lanes and turning left onto a highway with no median) 1.47 X (speed) X 8.0 (per pg. 660) = SD</td>
</tr>
<tr>
<td>4 Lane Major Road Divided – 18’ median (crossing 2 lanes + 18’)</td>
<td>See 2004 AASHTO, page 664 Based on 18’ median (widest median without provision for stopping) Page 664 says to add 0.5 seconds “for narrow medians that cannot store the design vehicle”. 18’ = 1 ½ Lanes to cross, or 7.5 + .5 + .75 = 8.75; therefore: 1.47 X (speed of approach roadway) X 8.75 = SD</td>
</tr>
</tbody>
</table>

**TABLE 2-8 INTERSECTION SIGHT DISTANCE CRITERIA**
Median Openings/Crossovers

(With and Without Connections)

In commercial and industrial areas where property values are high and rights-of-way for wide medians are difficult to acquire, a paved flush traversable median 10’ to 16’ wide is the optimum design. The shape of the median end should generally be symmetrical when the median width is less than 10’ and the median opening length is not excessive, but the bullet nose can be effectively used to reduce the opening. For a median width of 10’ or more, the bullet nose design should be used instead of a semicircular design at 3-leg and 4-leg intersections.

The length of the crossover and the shape of the median end are controlled by the width of the median and the turning radii. A wide median opening can be reduced at skewed intersections by utilizing modifications of the bullet nose design. Additional information may be obtained from the Access Spacing Table 2-2 and AASHTO’s A Policy on Geometric Design of Highways and Streets (Median Openings).

New crossovers must demonstrate that left-turn storage space is met. Use appropriate turning movement software for analysis (such as Auto-Turn).

Crossover Grades

On divided highways with depressed medians, there are generally three methods by which superelevation is determined for the opposing traffic lanes.

One method is for the median pavement edges to be held at the same, or close to the same elevation. A second method is for each baseline elevation to be approximately the same, with a corresponding difference in elevation of the median pavement edges. The third method is for the superelevation of all lanes to be obtained along a single plane. Thus, the grade of the lane on the outside of the curve is higher than the inside lane. The various methods are illustrated below.

![Method 1](METHOD_1.png)
![Method 2](METHOD_2.png)
![Method 3](METHOD_3.png)
The designer is to study the requirements of each particular situation. In the case of a facility without crossovers, the first method above is generally acceptable on superelevated curves. This will allow the median area to be properly graded without creating an adverse design situation.

Method 2 generally results in an undesirable situation and must be used with caution.

In a case where a crossover is proposed, particularly in conjunction with a connecting road within the limits of a superelevated curve, the designer shall pay particular attention to the patch which must be traversed by vehicles using the crossover.

In most cases, the application of the superelevation in a single plane (Method 3) is the acceptable method. This will allow a vehicle to cross from one lane to the other without negotiating several different gradients. As noted, herein, this will require the adjustment of the mainline grades.

The desirable grade on a crossover is between 0.5% and 5%. The maximum grade should never exceed 10% as safe turning movements above this level are difficult. It is especially important at locations, such as truck stops and other businesses generating large vehicular traffic, that crossover grades fall in the category of less than 5%. A desirable maximum algebraic difference of a crossover crown line is 4 or 5 percent, but it may be as high as 8 percent at the locations where there are few trucks or school buses and low speeds.

Additionally, sight distances must be checked for values shown in the Table 2-7 Intersection Sight Distance.

Any deviation from these values is to be brought to the attention of the State Location and Design Engineer.

The grade on a crossover is measured from the edge of shoulder to the edge of shoulder, unless left turn lanes are provided, in which case the grade is applied from the edge of pavement of the left turn lanes to the edge of pavement of the opposite left turn lane. This is more clearly shown in the following diagram:

![Diagram of Crossover with and without Left Turn Lanes]

In preparing plans for field inspection, the gradient at each crossover is to be plotted graphically.
**Intersecting Cross Road Grades**

The grade of a connecting facility must be carefully studied when approaching an intersection where the mainline is superelevated. A smooth grade tie-in is desirable, with sufficient area on a relatively flat grade for a vehicle to stop before entering the main roadway. Also, when a connection is on the outside of a superelevated curve, the grade must be designed so that the connection is visible to a driver on the main roadway desiring to turn onto the connections.

Every attempt must be made to provide an adequate area for this vehicular stoppage, giving full consideration to the horizontal and vertical sight distances.

The desirable tie-in is one that is no steeper than the pavement cross slope whether this is superelevated or the normal crown. The maximum difference between the pavement cross slope and the approach road grade shall not exceed 8% at stop intersections or 4% at continuous-movement intersections. The stoppage area should be a minimum of 50’ before beginning the steeper grade. (See AASHTO’s *A Policy on Geometric Design of Highways and Streets*).

**Roundabouts**

**Overview**

Roundabouts are circular intersections with specific design and traffic control features. These include yield control of all entering traffic (circulating vehicles have the right-of-way), channelized approaches, and geometric curvature to ensure that travel speeds are typically less than 30 mph (single lane 20-25 mph; double lane 25-30 mph).

Roundabouts are generally safer than other types of intersections for low and medium traffic conditions. These safety benefits are achieved by eliminating vehicle crossing movements through the conversion of all movements to right turns and by requiring lower speeds as motorists proceed into and through the roundabout. The potential for right angle and left turn head-on crashes is eliminated with single lane roundabouts. Single lane roundabouts are safer than double lane roundabouts due to more complex decisions for entering and especially for exiting a double lane roundabout.

While roundabouts usually require more right-of-way area at an intersection, compared to a traffic signal, they require less right-of-way area on the upstream approaches and downstream exits. At new intersection sites that will require turn lanes a roundabout can be a less expensive intersection alternative. Operating and maintenance costs are less than signalized intersections since there is no signal equipment. The roundabout has aesthetic advantages over other intersection types particularly when the center island is landscaped.

Because roundabouts treat all vehicle movements equally (each approach is required to yield to circulating traffic), a roundabout that will serve the intersection of a higher volume major roadway and a lower volume minor street (e.g. principal arterial vs. collector) can cause traffic delays and stopped queues on the major roadway.
Consequently, functional classification (hierarchy) of the intersecting roads needs to be assessed when considering the construction of a roundabout.

**VDOT Policy**

VDOT recognizes that roundabouts are frequently able to address the above safety and operational objectives better than other types of intersections in both urban and rural environments and on high-speed and low-speed highways.

Therefore, it is VDOT policy that roundabouts be considered when a project includes reconstructing or constructing new intersection(s), signalized or unsignalized. The Engineer shall provide an analysis of each intersection to determine if a roundabout is a feasible alternative based on site constraints, including right-of-way, environmental factors and other design constraints. The advantages and disadvantages of constructing a roundabout shall be documented for each intersection. The documentation shall include, at a minimum, the criteria outlined in this section.

When the analysis shows that a roundabout is a feasible alternative, it is considered the Department’s preferred alternative due to the proven substantial safety and operational benefits.

Roundabouts should not be considered as a feasible alternative when the following criteria exist:

- Where adequate horizontal and/or vertical approach sight distances cannot be met.
- When there are signalized intersections close to the proposed roundabout.
- Where high volume entrances are in close proximity (within 100’) to the outer edge of the inscribed diameter.
- Where left turns are not the predominant turning movement.
- When deemed unsuitable due to other engineering factors by the District or Central Roundabout Review Committee.

**Design/Resources**

The maximum daily service volume of a single-lane roundabout varies between 20,000 and 26,000 vehicles per day (2,000 - 2,600 peak hour volume), depending on the left-turn percentages and the distribution of traffic between the major and minor roads.

Roundabout designs shall be based on Federal Highway Administration Publication Number FHWA-RD-00-067, Roundabouts: An Informational Guide. See the following link: [http://www.tfhrc.gov/safety/00068.htm](http://www.tfhrc.gov/safety/00068.htm).

Additional information can also be found in VDOT’s Roundabout Brochure at [http://www.virginiadot.org/info/resources/Roundabouts.pdf](http://www.virginiadot.org/info/resources/Roundabouts.pdf) and on VDOT’s roundabout web site at [Roundabouts in Virginia](http://www.virginiadot.org/info/roundabouts).
Figure 2-11 illustrates roundabout design details including pedestrian and bicycle treatments. Common characteristics of acceptable roundabouts include:

- Domed center that is sufficiently clear to not compromise sight distance, and
- Paved traversable apron not less than 4 feet in width, the radius of which is sufficient to serve the turning radius of school buses and single unit design vehicles. If the percentage of trucks anticipated to use the road exceeds 5%, that radius should be sufficient to serve those vehicles.

Example Plan Sheets for Typical Single Lane Roundabouts can be accessed at: https://www.nysdot.gov/portal/page/portal/main/roundabouts/guide-engineers/examples

The documentation shall include, at a minimum, the criteria outlined in this chapter.

When roundabout design is proposed, the District Location & Design Engineer should be consulted.

The Approval Process for Roundabouts

Existing and Proposed Subdivisions - The District may review and approve roundabouts in subdivisions.

Secondary System – The District may approve up to a traffic design volume of 10,000 VPD. Roundabout designs in which the counts are beyond this volume should be submitted to the Central Office Roundabout Review Committee for review. The committee will make recommendations to the State Location and Design Engineer for approval or disapproval. Appeals of the State Location and Design Engineer decision will go to the Chief Engineer for resolution.

When a District receives a request for a roundabout from an outside entity, and the design volume is under 10,000 VPD but desires Roundabout Committee review and input, the submittal may be sent to the State Location and Design Engineer. It will be reviewed and comments and/or recommendations will be returned in a timely manner.

Primary or Urban System - The District will submit roundabout designs to the Central Office Roundabout Committee for review. The approval and appeals will be the same as used above for these roadway systems with one exception: urban systems will require approval of the Local Assistance Division Administrator as well as the State Location and Design Engineer.

The process listed above applies to:

- Roundabouts proposed through 6 year construction program.
- Roundabouts proposed during road safety improvements and/or upgrades.
- Roundabouts proposed by Counties, Localities, Consultants and Developers.
The submittal should contain and depict the following criteria:

- Approach Grades and sight distances.
- Inscribed diameter of circulatory roadway.
- Design vehicle (WB-50 or WB-67).
- Apron width, circulatory lane width and approach lane widths.
- Approach lane deflection and length of splitter islands.
- Pedestrian crossing locations.
- Pavement markings.
- Signing.
- Roadway Lighting (desirable).
- Nearest entrance locations and nature of property use.
- Initial or present and projected design year traffic count on all approaches.
- Turning movements for all directions.
- SIDRA Analysis on all approaches showing peak hour LOS in design year.
- Autoturn results showing off tracking of Design Vehicle.
- Is this facility designed as a bicycle Route?
- Are their accommodations made to bicyclists?

If for some reason, the District does not have capability to run the subject computer programs, the Roundabout Committee can provide assistance upon request.
Minimum Dimensions for Roundabouts and Circular Islands

<table>

All Roundabouts shall be designed in accordance with the design documents mentioned in Roundabouts section above.

FIGURE 2-11 ROUNDAABOUT DESIGN DETAILS

Accommodating Pedestrians and Bicyclists

According to the Commonwealth Transportation Board’s adopted Policy for Integrating Bicycle and Pedestrian Accommodations, bicycling and walking are fundamental travel modes and integral components of an efficient transportation network. Appropriate bicycle and pedestrian accommodations provide the public, including the disabled community, with

- Access to the transportation network;
- Connectivity with other modes of transportation; and
- Independent mobility regardless of age, physical constraints, or income.

Effective bicycle and pedestrian accommodations enhance the quality of life and health, strengthen communities, increase safety for all highway users, reduce congestion, and can benefit the environment. Bicycling and walking are successfully accommodated when travel by these modes is efficient, safe, and comfortable for the public. It is important that the consideration and provision of bicycling and walking accommodations be consistently incorporated into the decision-making process for Virginia’s transportation network.

The VDOT web site contains a number of resources on accommodating pedestrian and bicycle facilities as well as facility design guidelines.

VDOT’s Designated Bicycle and Pedestrian Accommodations provides design standards for bicycle and pedestrian facilities (e.g. designated bicycle lanes at least 4 feet in width, providing striping for bicycle lanes, asphalt or concrete sidewalks at least 5 feet in width, pedestrian islands at intersections and roundabouts).

Bicycle Facility Guidelines (web link) are presented in Section A-5, Appendix A of The Road Design Manual. Section 2E-3 of this Manual also provides Sidewalk Design Standards (web link) on sheet 7 in the Location & Design Division Instructional and Informational Memorandum IIM-LD-55.11.

Standards for Intersection Crosswalk Markings (web link) can be found on page 3B-27 in the Manual for Uniform Traffic Control Devices and Standards for Pedestrian and Bicycle Markings for Roundabouts (web link) are described on pages 3B-44 and 3B-45.

Figure 3-25 offers a basic illustration of these pedestrian and bicycle concepts along a highway corridor and at an intersection.

An Internal Bicycle and Pedestrian Task Force is responsible for ensuring consistent implementation of bicycle and pedestrian policies within VDOT, while the Bicycle Accommodations Review Team evaluates proposed plans to ensure consistency in bicycle and pedestrian facility design. For additional information see the State Bicycle and Pedestrian Program web page on the VDOT web site.
Managing Access to the Highway and Pedestrian/Bicyclist Safety

Numerous entrances and intersections create safety problems for pedestrians and bicyclists. Every entrance and intersection creates pedestrian-vehicle, bicyclist-vehicle and vehicle-vehicle conflicts. Pedestrians and bicyclists are especially vulnerable to vehicular left turns because they are small visual objects compared to vehicles and not clearly visible to drivers who are focusing on the opposing traffic when they begin a left turn. Left turns account for a high number of crashes with bicyclists and pedestrians.

Reducing the number of entrances and limiting access from one or more directions improves pedestrian and bicyclist safety:

- The number of conflict locations is minimized;
- Lowering the driver workload, as well as that of pedestrians and bicyclists, improves safety and simultaneously improves traffic flow.
- Pedestrian/bicyclist crossing is enhanced with median refuge areas;
- Accommodating the disabled is easier, as the need for special treatments at entrances is reduced; and

Figure 2-12 below illustrates how each entrance creates eight potential conflict points for pedestrians and bicyclists. Reducing the number of entrances and restricting left turn movements lowers these potential crash points.

FIGURE 2-12 REDUCING THE NUMBER OF ENTRANCE BENEFITS PEDESTRIANS AND BICYCLISTS

Source: Transportation & Land Development 2nd Edition 2003, Koepke and Stover
Once the pattern of entrances and intersections is established, it is difficult to retroactively reduce, consolidate, or eliminate existing entrances to make existing roads more attractive to bicyclists and pedestrians.

However, midblock crosswalks can be considered to provide locations for pedestrians and bicyclists to cross arterials between intersections where pedestrian/bicyclist attractors are located on opposite sides of a roadway. Midblock crossings can provide:

- Visual cues to allow approaching motorists to anticipate pedestrian activity and unexpected stopped vehicles, and
- Reasonable opportunities to cross during heavy traffic periods, when there are few natural gaps in the traffic streams.

A traffic engineering investigation study will need to evaluate the proposed location and design. Conditions to examine include: sight distance, speeds, volumes, crash experiences, illumination, number and type of pedestrians, and the location of pedestrian generators. Design considerations include median refuge area, pavement markings, advance warning signs for vehicular traffic, and coordinating potential pedestrian/bicyclist activated crossing signals with the traffic signal timing on the highway so as to not interfere with traffic progression.

The Federal Highway Administration’s web site contains a variety of research reports on techniques for improving pedestrian and bicyclist safety along the highway:

http://www.tfhrc.gov/safety/pab.htm

SECTION 3 – TURNING LANES

Left and Right Turn Lane Criteria

As a general policy, left-turn lanes are to be provided for traffic in both directions in the design of all median crossovers on non-access controlled four-lane or greater divided highways using controls as shown in Figure 3-1 and adjusted upward as determined by Figure 3-3 or by capacity analysis for left-turn storage.

Left-turn lanes should also be established on two-lane undivided highways where needed for storage of left-turn vehicles and/or prevention of thru-traffic delay as shown in Figure 3-1 and adjusted upward as determined by Table 3-1 and Figure 3-4 through 3-21 or by capacity analysis for left-turn storage.

<table>
<thead>
<tr>
<th>LENGTH OF STORAGE</th>
<th>TAPER - Rural and Urban</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rural - For Design Speeds 50 MPH or Higher</td>
<td>*L - 200’ min. (For 240 or fewer vehicles during peak hour, making turn)</td>
</tr>
<tr>
<td></td>
<td>- For Design Speeds 35 MPH or Higher **T - 200’ Min.</td>
</tr>
<tr>
<td></td>
<td>- For Design Speeds 45 MPH or Less than **T - 100’ Min.</td>
</tr>
<tr>
<td></td>
<td>*Distance L to be adjusted upward as determined by capacity analysis for Left and Right Turn Storage. **Tapers are to be straight-line unless local policy requires reverse curves. In congested areas the taper length may be reduced to increase storage length.</td>
</tr>
<tr>
<td>Urban - Length determined by capacity analysis for Left and Right Turn Storage</td>
<td></td>
</tr>
</tbody>
</table>

**FIGURE 3-1 LEFT AND RIGHT TURN LANE CRITERIA**

(To be used for divided and undivided highways)
(However, VDOT minimum standards for storage length (45 mph) is 100 feet)

Taper rates: 8:1 for design speeds up to 30 mph and 15:1 for design speeds between 35 and 50 mph. (Source: 2004 AASHTO “Green Book”, page 716).

Note: Taper lengths shown above were compiled using these formulas and were rounded up.
For Four-Lane Highways
*Dimension "L" to be adjusted upward as determined by Figure 3-3 or by capacity analysis for left-turn storage lanes on four-lane or greater (divided) highways.

**Figure 3-2 Left and Right Turn Storage and Taper Lengths**

For Two-lane Highways
Dimension "L" to be adjusted upward as determined in Figures 3-4 through 3-24 or by a capacity analysis for left-turn storage. A capacity analysis is defined as a detailed analysis of the location in accordance with the guidelines contained in the current issue of the Highway Capacity Manual for intersection capacity and signalization requirements.

In general, when left-turn volumes are higher than 100 VPH, an exclusive left-turn should be considered.

Dual left-turn lanes should be considered when left turn hourly volumes exceed 300 VPH.
Warrants for Left Turn Storage Lanes on Four-Lane Highways

When the Average Running Speed on an existing facility is available, the corresponding Design Speed may be obtained from IIM LD-117.

For plan detail requirements when curb and/or gutter are used, see VDOT’s Road Design Manual, Section 2E-3 on the VDOT web site:

Left-turn lanes should also be established on two-lane highways where traffic volumes are high enough to warrant them.
**Warrants for Left Turn Storage Lanes on Two-Lane Highways**

The warrants in table below are taken from the 2004 AASHTO “Green Book”, Page 685, Exhibit 9-75. They were derived from Highway Research Report No. 211, Figures 2 through 19, for required storage length determinations.

The No. 211 study was undertaken to provide consistent volume warrants for left-turn storage lanes at unsignalized intersections.

* USE DESIGN SPEED IF AVAILABLE, IF NOT USE LEGAL SPEED LIMIT.

Example:

Two-lane highway with 40-MPH operating speed

Opposing Volume (VPH) - 600
Advancing Volume (VPH) - 440
Left-Turn Volume (VPH) - 44 or 10% of Advancing Volume

With opposing volume (VPH) of 600 and 10% of advancing volume (VPH) making left turns, and advancing volume (VPH) of 305 or more will warrant a left-turn lane.

The left turn lane warrant chart on page 45 denotes that a 100' storage length is required.
The figures below provide warrants for left-turn storage lanes on two-lane highways based on 5 to 30 percent left-turn volumes and design speeds of 40, 50, and 60 MPH. Additional storage length is required for 10 to 50 percent truck volumes.

Intersections with poor visibility and/or a bad accident record may require the designer to use engineering judgment when volume conditions alone do not warrant a storage lane.

Additionally, the functional classification of the highway shall be considered so that the impact of turning movements on highways intended to serve through traffic is minimized.

FIGURE 3-21
Medians

Channelization: Positive channelization should be provided for all median openings. Standard striping in accordance with the Manual on Uniform Traffic Control Devices (MUTCD) should be used for all openings and speed change lanes in medians without raised channelization. Medians with raised channelization require mountable curbing on the nose section and the mountable curb should be marked with yellow paint containing retro-reflective glass beads. If new curbing is required in addition to the nose sections, it should match the existing curb type of the median. Median openings on rural, high-speed highways should be signed with Do Not Enter and One-way) signs.

U-turns: The median width may be designed to permit U-turn movements. If a facility is too narrow to safely permit a U-turn, these movements should be addressed in design (such as flare outs on page 19) or restricted through signage. Sign use and placement require Department approval.

Pavement: Median paving should be full depth and match the pavement section design of the existing roadway.

Drainage Function: Medians frequently provide a conveyance, detention or retention function for roadways. The installation of a median opening should not reduce the conveyance or storage capacity of the median.

Directional Median Opening for Left Turns and U-Turns

A directional median opening for left turns and U-turns limits movements at median openings to specific turns only; the physical design actively discourages or prevents all other movements.

- The technique can be applied to unsignalized median openings on multilane divided urban and suburban streets.

Special Considerations

- The minimum width of a median nose has commonly been 4 feet. AASTHO recommends a minimum median width of not less than 4 feet and 6 to 8 feet wide is preferable where pedestrians may be present.

- Narrow median noses are difficult to see especially at night and in inclement weather. Reflectorized paint is of little help as it rapidly becomes dirty and loses its limited reflectivity. Reflectorized traffic buttons or reflectorized pylons help but lack the mass necessary to provide good target value.
• Carefully selected landscaping is the most effective way to ensure high visibility of the median and median openings.

• Landscaping of the median nose for visibility is especially important where long left-turn lanes are used. The choice of vegetation and the landscaping design must ensure that sight distance is not obstructed.

• Overlapping of the separators of a directional median opening restricts movements to the intended left turn or U-turn.

• Directional median openings will accommodate U-turns by automobiles where the separation is at least 4 feet wide and there are three opposing lanes. Where there are two opposing lanes a triangular flare of 10 feet along the intersecting roadways and at least 20 feet along the major roadways will allow an automobile to execute a U-turn.

Advantages

• The directional median opening for left turns and U-turns improves safety by limiting the number and location of conflict points and by prohibiting direct crossing.

• Right-angle crashes are avoided because vehicles are prevented from crossing where the median width is not sufficient for drivers to cross one-traffic stream at a time.

Disadvantages

• Cross-median movements are limited to specific locations and to specific turns.

• It is not practical to design for U-turns executed by large vehicles in all directions.
Illustration of Directional Median Opening for Left Turns and U-Turns

FIGURE 3-22 ILLUSTRATION OF DIRECTIONAL MEDIAN OPENING FOR LEFT TURNS AND U-TURNS

Examples

- Some states make extensive use of directional median openings. Preference is given to left turns and U-turns from the major roadway. Existing full median openings are reconstructed as directional openings as part of resurfacing projects or reconstruction projects. The minimum width of 2 feet can be accommodated in the standard 16 foot raised median. Separators are overlapped by at least 2 feet.

- The Michigan DOT has pioneered a variation of the directional median opening called the Michigan U—Turn. This design involves the installation of directional openings near signalized intersections.
Right Turn Lanes

An exclusive right-turn lane should be considered when the warrants on pages 62 and 63 are met. Double exclusive right-turn lanes may be provided when capacity analysis warrants. Safety implications associated with pedestrians and bicyclists should always be considered.

These guidelines are to be used as an aid in selecting appropriate treatments for right turn movements. (Reference material attained from Virginia Highway and Transportation Research Council report "The Development of Criteria For the Treatment of Right Turn Movements on Rural Roads" dated March 1981).

1. Number of Lanes – Guidelines are differentiated on the basis of the number of lanes on the major roadway. The minor roadway is a 2-lane road. Discussion on both figures is provided. All volumes refer to the volumes on the approach under consideration for right turn treatments.

2. Radius Treatment – Refer to guidelines for right turn treatment on 2-lane roadways. The predominant treatment for 2-lane roadways is the radius. Arterial roadways tend to carry higher volumes of traffic traveling at higher speeds as compared to local roadways.

The traffic on local roadways tends to include a higher number and percentage of right-turning vehicles than that on arterials. An adjustment is needed to permit local roadways to handle more right turns (at lower speeds) compared to arterial roads. The following adjustment is made for posted speeds at or under 45 mph.

Adjusted Number of Right Turns = Number of Right Turns - 20 for number right turns > 40 and total volume < 300

For example, Total volume = 200 vph, Right turn volume = 70 vph and Posted speed = 40 mph. Then adjusted number of right turns - r = 70 - 20 = 50. Therefore, projecting a total volume 200 vph and r=50 vph in the table, a radius is recommended for the right turn treatment.

3. Four-lane Roadways – Four-lane roadways tend to have a taper or full-width lane to facilitate right turn movements. Many of these roads are divided highways with a speed limit of 55 mph.

4. Curb Channelized Island – Curb channelized island should be considered to separate right turn lanes from thru traffic based on capacity analysis.
5. **Other factors** – The selection of a treatment for right turn movements may be influenced by sight distance, availability of right-of-way, grade, and angle of turn. Although these factors are not incorporated in the guidelines, they should be given consideration. The guidelines should be used unless the Engineer at the District or Residency determines that special treatment is necessary due to other factors.

6. **Data collection procedures** – In order to employ these guidelines, peak hour volume data must be provided.

**Right / Left Turn Lanes may be required beyond these guidelines at the discretion of the District Administrator or designee.**

Conditions for providing an exclusive right turn lane when the right turn traffic volume projections don’t exceed the guidelines:

- Facilities having a high volume of buses, trucks or trailers.
- Poor internal site design of an entrance facility causing potential backups in the through lanes.
- Heavier than normal peak flows on the main roadway.
- High operating speeds (such as 55 mph or above) and in rural locations where turns are not expected by through drivers.
- Highways with curves or hills where sight distance is impacted.
- Higher functionally classified highways shall be considered so that the impact of turning movements on highways intended to serve through traffic is minimized.
Appropriate Radius required at all Intersections and Entrances (Commercial or Private).

**LEGEND**

**PHV** - Peak Hour Volume (also Design Hourly Volume equivalent)

**Adjustment for Right Turns**

For posted speeds at or under 45 mph, PHV right turns > 40, and PHV total < 300.

Adjusted right turns = PHV Right Turns - 20

If PHV is not known use formula: PHV = ADT x K x D

\[ K = \text{the percent of AADT occurring in the peak hour} \]
\[ D = \text{the percent of traffic in the peak direction of flow} \]

Note: An average of 11% for K x D will suffice.

**FIGURE 3-23 GUIDELINES FOR RIGHT TURN TREATMENT (2-LANE HIGHWAY)**
Appropriate Radius required at all Intersections and Entrances (Commercial or Private).

**LEGEND**

**PHV** - Peak Hour Volume (also Design Hourly Volume equivalent)

**Adjustment for Right Turns**

If PHV is not known use formula: \( PHV = ADT \times K \times D \)

- \( K \) = the percent of AADT occurring in the peak hour
- \( D \) = the percent of traffic in the peak direction of flow

Note: An average of 11% for \( K \times D \) will suffice.

**FIGURE 3-24 GUIDELINES FOR RIGHT TURN TREATMENT (4-LANE HIGHWAY)**
Acceleration Lanes

Acceleration lanes should consist of a full-width lane and a transition taper. Acceleration lanes should be designed so that a turning vehicle will reach a speed between 75 and 80 percent of the highway posted speed at the point where the full-width lane ends and transition taper begins.

- Acceleration Lane: A stop condition should be assumed when determining the length of an acceleration lane for an at-grade access. The length of an acceleration lane is the same for a right-turn acceleration lane or for a left-turn acceleration lane.

- Transition Taper: Acceleration tapers should be straight line tapers with rounded beginning and ending points.
FIGURE 3-25 TYPICAL APPLICATION WITH SIDEWALKS AND BIKE LANES WITH RIGHT-TURN DECELERATION LANES (CURB AND GUTTER SECTION)

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.
SECTION 4 – ENTRANCE DESIGN

Entrance Design Principles

Entrances are, in effect, at-grade intersections and should be designed consistent with the intended use. The number of crashes is disproportionately higher at entrances than at other intersections; thus their design and location merit special considerations. Entrances should not be situated within the functional area of an intersection or in the influence area of an adjacent entrance. The functional area extends both upstream and downstream from the physical intersection area and includes the longitudinal limits of auxiliary lanes.

Entrance Angle: The entrance centerline should be perpendicular to the state highway centerline and extend tangentially for a minimum distance of 40 feet beyond the near-side edge line. An acute angle between 60 degrees and 90 degrees may be permitted if significant physical constraints exist. Acute angles less than 60 degrees shall require special approval of the Department.

Entrance Radius: The entrance radius should be designed to accommodate the design vehicle expected to use the entrance on a daily basis.

**TABLE 4-1 DESIGN VEHICLE AND TURNING RADIUS BY LAND USE**

Note: “with Separate Truck Access” indicates truck prohibition from primary access.

Entrances into mixed use developments will be designed to accommodate the largest design vehicle expected to use that entrance.
Private Entrances (Existing State Highways)

1. Curb and Gutter Private entrances
   At all private entrances, standard entrance gutter (Std. CG-9D; other options are CG-9A or CG-9B) shall be used with Std. CG-6 or CG-7 curb and gutter. A special design entrance gutter shall be submitted for approval when roll top curb is used.

2. Ditch Section Private Entrances
   All private entrances shall be designed to serve no more than two individual lots. All private entrances shall be designed and constructed as shown in Figure 4-1. Entrance radius shall be 20’ minimum. All entrance pipe culverts will be sized to accommodate the run-off expected from a 10-year frequency storm.

   All private entrance grades shall start back of the shoulder line. If drainage is necessary, the ditch line may be moved back to provide 9 inches minimum cover over pipe. Entrances shall be at least 12’ wide and shall be tied smoothly into the roadway surface. The entrance surface shall extend from the edge of the roadway to the right-of-way line. The entrance surface can be crusher run aggregate (gravel), asphalt, concrete, etc.

3. Private Entrance Grades
   In the interest of assuring an adequate, convenient, and safe access to public roads, VDOT recommends the grades along private entrances not exceed 10%.

---

**FIGURE 4-1 PRIVATE ENTRANCE DETAIL**
4. **Modification of an Existing Entrance**
   When an existing street is re-developed and modification of an existing entrance is required, the entrance pavement shall be extended to the right-of-way line or the extent of disturbance to the existing entrance.

5. **Private Entrance Cut/fill Detail**
   For cut/fill details, see the VDOT Road and Bridge Standards, Section 600, Standard PE-1 web link: [http://www.virginiadot.org/business/locdes/2008_standards_complete_sections.asp](http://www.virginiadot.org/business/locdes/2008_standards_complete_sections.asp)

**Commercial Entrances**

All commercial entrances shall be designed in accordance with the entrance design diagrams Figures 4-8 to 4-15 to promote safe and efficient movement of vehicles in the entrance and on state highways.

An access shall not be approved for parking areas that require backing maneuvers within state highway right-of-way. All off-street parking areas must include on-site maneuvering areas and aisles to permit vehicles to enter and exit the site in forward drive without hesitation.

**Entrance Medians:** Entrance medians should be used when two or more lanes are required for both the entering and the exiting movements at the entrance.

- Entrance medians shall have a minimum width of 4 feet.

- All curbing within the highway clear zone shall be in accordance with VDOT’s *Road and Bridge Standards*, or as approved by the District Administrator or designee, and appropriate for the operational speeds of the facility. Non-regulatory signs shall not be placed in the portion of a entrance median located within the right-of-way, or within the highway clear zone, and shall not restrict intersection sight distances.

- An entrance median should not contain structures, signs, or landscaping which restrict sight distance. The minimum size of a entrance median island is 100 square feet.

**Entrance Throat:** The entrance throat should be designed to facilitate the movement of vehicles off the highway to prevent the queuing of vehicles on the traveled way. The throat length is based on the traffic a development will generate, not the characteristics of the abutting highway. The more traffic using the entrance, the greater the number of ingress/egress lanes will be needed within the entrance, which determines the length of the entrance throat. Both sides of throat need to be protected.
The length of the entrance-side throat needs to equal the exiting throat. When entering vehicles stop to turn left there must be sufficient queuing length to prevent other entering vehicles from backing up on to the highway. Minimum connection throats are provided in the table below.

Entrance throats apply to entrances to commercial uses, corner clearance establishes the “Throat” of a minor street intersecting a major street.

**TABLE 4-2**

Source: Transportation & Land Development 2nd Edition 2003, Koepke and Stover

To assure that entrances are designed to provide for safe and efficient movements, it is necessary to pay attention to critical dimensions and design features listed below.

- Radius of curved approach/exit of entrance.
- Flare size of angled approach/exit of entrance.
- Entrance Distance or spacing between entrances.
- Corner Clearance measured from a major intersection.
- Angle of entrance.
- Sight distance length of roadway visible to the driver required for vehicles to make safe movements.
- Entrance location in relation to other traffic features such as intersections, neighboring entrances, and median openings.
- Entrance throat distance needed into site to transition vehicles to the internal circulation system of the site.
- Right turn lanes to separate through and turning traffic on roadways to facilitate right turns into the entrance.

**Entrance Pavement:** The type and depth of the pavement shall be clearly indicated on the plans and/or permit application. The pavement of commercial entrances, turn lanes and tapers shall be of asphalt, concrete, or pavers that is of a construction comparable to the pavement of the adjacent roadway.

**Access Vertical Alignment:** The vertical alignment of all access locations should be designed to minimize vehicle bounce and prevent high-centering of vehicles with a maximum clearance of 4 inches. The maximum grade for an entrance should be 8% for all commercial entrances.
Steeper access entrances require District Administrators approval. A level area (maximum 2% grade) 20 feet in length should be provided at each access to ensure proper sight distance from the access. The level area is measured from the highway edge of pavement or from the back of sidewalk, whichever is appropriate based on site-specific conditions.

**Entrance Cuts:** The maximum vertical curve, crest or sag, shall have a maximum 4-inch vertical offset over a 10-foot chord length. A standard vertical curve should be designed for all entrance profiles that exceed 3.3%.

**Entrance Drainage:** Drainage shall be considered in the design of entrance grades. Roadways and curb-and-gutter sections that convey storm water runoff within the roadway prism should designed in accordance with department standards. Site runoff into state right-of-way should be minimized.

**Width:** All commercial entrances shall have a width sufficient for the particular land use and anticipated traffic flow with a minimum width of 16 feet for a one-way drive and 30 feet for a two-way drive. A two-way commercial entrance on a local street shall have a minimum width of 24 feet. The maximum width should be 20 feet for a one-way drive and 40 feet for a two-way drive. These widths should be measured at right angles to the centerline of the entrance at the right-of-way line. Entrances with multiple lanes or median may require additional width. For subdivision streets, radii width and angle should be in accordance with Subdivision Street Design Guide in the Road Design Manual, Appendix B (1), at web link.

**Radii:** All commercial entrances should have radii large enough to accommodate the largest design vehicle that will use it without creating undue congestion or hazard on the through highway (See Table 4-1). The minimum entrance radius allowed should be 25 feet and the minimum exit radius allowed should be 25 feet.

Where on-street parking is allowed near the commercial entrance, the effective radius for the entrance shall be used. Typically the effective radius will be the actual radius of the entrance curbing plus the width of the parking lane (for example 12.5 ft curb radius plus 8 ft wide parking lane resulting in an effective radius of 20.5 feet).

For subdivision streets, radii width and angle should be in accordance with Subdivision Street Design Guide in the Road Design Manual, Appendix B (1). See above web link.

**Auxiliary Lanes and Tapers** - When a land use will generate high traffic volumes, auxiliary lanes and tapers may be required. Auxiliary lanes and tapers shall be located within right-of-way.

**Angled Entrances** - When the property owner desires to construct dual commercial entrances at other than 90 degrees to the centerline of the road, an entrance on the right side as approaching should not have less than a 60 degree angle with the centerline of the road.

**Profile** - All commercial entrances should be built to a sidewalk elevation at the right-of-way line. Beyond the right-of-way line, the grade should not exceed 8 percent. Entrance configurations are shown starting at Figure 4-8.
Pedestrian Accommodation – Design criteria for accommodating sidewalks at commercial entrances (by providing pedestrian access routes across the entrance) are presented in diagram CG-11 in the Road and Bridge Standards at the following web link: http://www.virginiadot.org/business/locdes/2008_standards_complete_sections.asp.

* Low Volume Entrance – Certain design characteristics are reduced for a low volume entrance along highways with shoulders. Site requirements are:
  
  - Maximum highway vehicles per day: 5,000
  - Maximum entrance vehicles per day: 200
  - Maximum entrance percent truck trips of vehicles per day: 10%

For low volume entrances the minimum entrance throat depth is 25 feet; minimum radii is 25 feet with curb/gutter or curbing not required; entrance width is 18 feet minimum and 30 feet maximum; and minimum angle of entrance is 60 degrees, 90 degrees preferred. See Figure 4-15 for low volume entrance design illustration.

Commercial Entrance Location Criteria

Entrances shall be placed at locations that provide adequate intersection sight distance. These locations often occur at the top or bottom of inclines. In hilly areas, proper locations can be at a premium, and shared access might be necessary.

Entrances shall not be placed within the functional area of any intersection. Greater spacing may be required due to stacking requirements of the approaches to the intersection. This can be particularly evident around signalized intersections.

![Figure 4-2 Physical and Functional Areas of Intersection](Source: FHWA, National Highway Institute Course No. 15255)
AASHTO specifically states that “a driveway should not be located within the functional boundary of an intersection”. AASHTO does not present guidelines as to the size of the functional area of an intersection; however the size must be much larger than the physical area (see Figure 4-2). The functional area should be composed of the distance traveled during the braking Perception-Reaction Time plus the distance required to move laterally and come to a stop plus any required storage length (see Figure 4-2A). The minimum maneuver distance assumes that the driver is in the proper lane and only needs to move laterally into a right turn or left turn bay.

\[
\begin{align*}
  d_1 &= \text{distance traveled during perception-reaction time (PRT) (2.5 sec. x Design Speed in ft/sec.)} \\
  d_2 &= \text{distance traveled while driver decelerates and maneuvers laterally (Taper length see Figure 3-1)} \\
  d_3 &= \text{storage length (See Figure 3-1)}
\end{align*}
\]

**FIGURE 4-2A FUNCTIONAL AREA OF INTERSECTION**

Source: 2004 AASHTO Green Book
Commercial Entrance Sight Distance

Entrances shall be located to provide adequate intersection sight distance. Minimum intersection sight distance criteria are provided below. The line of sight establishes the boundary of a sight triangle within which there should be no sight obstruction. At any location where the sight line leaves the right-of-way, a permanent easement must be maintained, and the area must be graded and landscaped such that sight distance is not compromised, for a commercial entrance to be approved. (For an Appeals Process, see Access Management Regulations: Minor Arterial, Collectors, and Local Streets, 24VAC30-73-50 B).

Offsets: Improvements on public or private property adjacent to the right-of-way should be located so that parking, stopping, and maneuvering of vehicles within the highway right-of-way will not occur. The minimum distance from the right-of-way line for all structures and sight obstructions should be the clear zone. At all entrances and intersections, an adequate sight triangle shall be provided. The minimum setback point for the sight triangle should be 14.5 feet from the near-side extended highway edge of pavement.

All site plans for proposed developments shall show the location of all proposed and existing entrances within the area of the proposed development. The location of all of the proposed entrances shall be reviewed to determine if proper spacing will be maintained.

Commercial Entrance Channelization

Figure 4-4 presents illustrations of commercial entrance channelization island options to prevent left turn ingress and/or egress movements to create a right-in and/or right-out entrance on an undivided highway. A median is more effective for preventing left turn movements and may be a design alternative to a channelization island. See Medians in section 3 for additional information.
Commercial Entrance Spacing

Access management increases the spacing between entrances, thus reducing the number and variety of events to which drivers along the corridor must respond. Close spacing between unsignalized entrances forces the driver to watch for ingress and egress traffic at several locations simultaneously. Increased spacing translates into fewer accidents, savings in travel time, and preservation of corridor capacity.

Entrances should be located to limit interference with the free movement of roadway traffic, and to provide the most favorable sight distance and entrance grade. No direct access entrance should be located in the operational area of a signalized intersection. Entrance spacing shall be based on spacing standards in Table 2-2.

Corner Clearance on a Minor Side Street

It is important to think of the operational impacts of entrance placement on side streets where they intersect with major roadways. The operational character of the traffic turning from the main roadway onto the minor side street as well as the expected queues on the side street, help determine how far to place the closest side street entrance from the intersection (the major roadway will have the higher functional classification or if the same classification, will have the higher traffic volume).

Moving the basic entrance conflict area away from the vicinity of an intersection can be accomplished by regulating the distance between a crossroad intersection and the nearest entrance location. The intent is to prevent queued vehicles from backing up into the highway or blocking entrances near the intersection. The major effect is that vehicles will be delayed less by standing queues at signalized intersections.

Corner clearance is defined as the distance, measured perpendicular to the major roadway, from the nearest edge of an entrance on the minor side street to the nearest edge pavement of the major roadway intersection.

In most instances, the minimum corner clearance will be governed by the intersection sight distance. Minimum entrance setbacks should be considered at individual intersections, and should be based on typical queue lengths that still allow sufficient movement to and from an entrance.

It is important to note that the Table 2-2 entrance and intersection spacing standards are measured from the centerlines of the intersection and the entrance rather than edge of pavement. As a result, the Table 2-2 spacing measurement may result in a distance that is less than the corner clearance. The greater of the spacing standards and the corner clearance will apply to protect intersection operation.
Similar to the placement of an entrance on the main roadway, conflicts for the existing vehicles for the side street entrance must be considered. Figure 4-3 illustrates the concept of corner clearance.

For the right turn out of the side street entrance (flow A), the vehicle approaching from the left (flow C) must be considered. The greater the radius (R) for right turning vehicles from the main roadway, the faster they will be approaching the side street entrance. For the driver exiting the side street entrance to go left (flow B) or right (Flow F) or to enter the opposite entrance (Flow E), the length of the queue at the main intersection must be considered to assure there is enough room that the entrance will not be blocked by queue D.

The minimum downstream corner clearance is 225', which equals the intersection sight distance for 20 mph (see Table 2-7). Additional length will be required as directed by the Engineer at the District or Residency if the intersection is signalized or future signalization is anticipated.

The minimum upstream corner clearance will be the greater of 225' + W or the queue D.

FIGURE 4-4 COMMERCIAL ENTRANCE CHANNELIZATION ISLAND OPTIONS
Entrance Connections on Opposite Sides of a Roadway

Closely spaced entrances on opposite sides of an undivided roadway or a roadway with two-way left-turn lanes (TWLTL) result in “jog” maneuvers, instead of separate and distinct left-turn and right-turn maneuvers (see below). They can also result in conflicting left-turns. Separation of the access connections results in their functioning as separate T-intersections (3-way intersection) that have relatively low crash potential.

FIGURE 4-5 ENTRANCE CONNECTIONS ON OPPOSITE SIDES OF A ROADWAY
Entrance Consolidation (Shared Use Entrances)

Shared Use Entrances are used to reduce the number of access points along a corridor while maintaining reasonable access to adjacent land uses. A Shared Use Entrance generally serves only two parcels.

A shared use entrance may be constructed if both property owners abutting a common property line agree. This encourages adjacent property owners to construct shared entrances in lieu of separate ones. Strategies for implementing this access control measure include closing existing entrances or authorizing joint-use ones. The feasibility of this measure should be viewed at the preliminary, site plan review and the permit-authorization stages. A shared access drive will result in a reduction in the concentration of entrances along a roadway, thus reducing the frequency and severity of conflicts.

The physical means by which access can be consolidated between two adjacent properties involves the construction of a joint-use entrance between the two properties. It is recommended that both property owners own the shared access drive. That is, the entrance should straddle the property line dividing the two establishments. The resulting joint-use parking area should be accompanied by an efficient internal circulation plan.

Shared Entrances and Internal Site Interconnection

If a group of smaller developments share access, the driver needing to turn left across heavy volumes can usually find an access that is signalized, allowing safer left turns. Having good cross parcel access also maximizes the number of well designed unsignalized entrances that have good visibility and are located in such a way to take advantage of sufficient gaps in traffic from a nearby signal. Joint entrances and cross access especially help the small corner lots and out parcels. On small corner parcels left turn accessibility may be a problem and access to parcels may be limited to right in/right out or similarly restricted movements.

FIGURE 4-6 SHARED ENTRANCE AND INTERNAL SITE CONNECTION
Frontage Roads

Frontage or service roads may be constructed by VDOT where justified by existing or anticipated traffic needs, right-of-way requirements, etc. within funds available.

Where frontage or service roads have not been constructed by VDOT, the Department may cooperate with others in the construction of service roads to promote highway safety and provide suitable locations for public utility services.

VDOT may furnish assistance if the construction of a frontage road will provide significant public service and eliminate undesirable ingress and egress through the establishment of safe and properly spaced access points.

Frontage roads constructed in cities, municipalities, or towns of more than 3,500 or along Primary routes in those counties which maintain their Secondary roads shall meet all minimum VDOT standards or the standards of the city, town or county as provided by ordinance.

When frontage or service roads are constructed by someone other then VDOT, the following conditions shall apply:

<table>
<thead>
<tr>
<th>If the road is Constructed on...</th>
<th>Then the construction or use must...</th>
<th>And...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing State Right-of-Way</td>
<td>Conform to such rules, regulations, standards, specifications, and plans as may be approved by VDOT and authorized by issue of a permit</td>
<td>The cost of the construction is fully borne by others.</td>
</tr>
<tr>
<td>Land Outside Existing State Right-of-Way</td>
<td>Conform to such rules, regulations, standards, specifications, and plans, as may be approved by VDOT</td>
<td>The land must be dedicated to public use if the road is to be accepted into the highway system and maintained by VDOT.</td>
</tr>
<tr>
<td>Then...</td>
<td>VDOT will accept as a part of the appropriate highway system, those service roads constructed by others in accordance with above criteria.</td>
<td></td>
</tr>
</tbody>
</table>

VDOT will maintain the roads in accordance with maintenance standards established for such classes of roads.

The cost of maintaining frontage roads shall be charged to the route and section of mainline highway which it serves unless it forms an integral section of another route.

Limits of Maintenance Responsibility for Private and Commercial Entrances

- Edge of Pavement
- Normal Shoulder Width
- Private Entrance
- Right of Way
- Commercial Entrance

Department's responsibility for maintenance

Landowner's responsibility for maintenance

FIGURE 4-7
Standard Private Subdivision Road / Street Entrance

**FIGURE 4-8 STANDARD PRIVATE SUBDIVISION ROAD / STREET ENTRANCE**

**Note:** All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board's “Policy for Integrating Bicycle and Pedestrian Accommodations”.

**PRIVATE SUBDIVISION ROAD ENTRANCE DESIGN ALONG STATE HIGHWAY WITH SHOULDERS**

**Note:**
- Entrance details shown on this sheet may be modified to meet specific site requirements as directed or approved by the engineer, when based on sound engineering practices.
- All entrance grades shall start back of the shoulder line. If drainage is necessary, the ditch line may be moved back to provide at least 6' of cover over pipe, as shown at right.
- Entrance shall or paved to a minimum width of 26'.
- Entrance grades are to be smoothly tied into the roadway by rounding as necessary.
- Minimum radius to be 20'. Increased radius may be required by local conditions.
- Administrator or Regional Traffic Engineer.
- Entrances in fill to be same as above except location of culvert (when necessary).

For Subdivision Streets and Alleys, care should be in accordance with Subdivision Street Design Guide in the Road Design Manual, Appendix B.
COMMERCIAL ENTRANCE DESIGNS ALONG HIGHWAYS WITH SHOULDERS

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.

FIGURE 4-9 COMMERCIAL ENTRANCE DESIGNS ALONG HIGHWAYS WITH SHOULDERS
Commercial Entrance Designs along Highways with Curb and Gutter

FIGURE 4-10 COMMERCIAL ENTRANCE DESIGNS ALONG HIGHWAYS WITH CURB AND GUTTER

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.

LETTER SYMBOL | DIMENSIONS
--- | ---
A | As determined by the Engineer
B | 100' or greater
C | See Entrance Throat Table 4-2 and Corner Clearance Figure 4-3.
F | 48' or greater
G | 12'
U | 25' - 50' The radius selected shall accommodate the anticipated type of vehicle usage. Larger radius should be selected when the predominant vehicle is larger vehicles are anticipated; however, in no case shall radius be less than 25'.
W | 30' - 40'
Y | 90° Preferred
 | 60° Minimum

* For Subdivision Streets and Alleys, radius, width and angle should be in accordance with Subdivision Street Design Guide in the Road Design Manual, Appendix B.

Notes:
Entrance details shown on this sheet may be modified to meet specific site requirements as dictated or approved by the Engineer so the Residency of Counties, when based on sound engineering principles.

An Accessible route as defined in Section 102.2021 in the Code of Va. is present, curb ramps in accordance with Std. CG-12 will be provided.
Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board's "Policy for Integrating Bicycle and Pedestrian Accommodations."
Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.
Commercial Entrance Designs along Highways with Curb and Gutter at Intersection

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.

FIGURE 4-13 COMMERCIAL ENTRANCE DESIGNS ALONG HIGHWAYS WITH CURB AND GUTTER AT INTERSECTION

LETTER SYMBOL DIMENSIONS
A As determined by the Engineer
B 100' or greater
C See Entrance Throat Table 4-2 and Clearances Figure 4-3;
D 48' or greater
E 12'
F See Spacing Table 2-2
G 225' or greater (additional length will be required as directed by the Engineer in the final plans and construction)
H See Clearances Figure 4-3.

U* 25'-50' The radius selected shall accommodate the anticipated type of vehicle usage, larger
I* 90' Preferred
J* 80' Minimum
K* For Subdivision Streets and Alleys, radius width and angle
L* All details shown on this sheet may be modified to meet specific project requirements
M as directed by the Engineer in the
N* Access Road or as defined in Section
O 15.2.2.01.1 of the Code of Va. It is the responsibility of the Engineer to ensure that the designs are consistent with the requirements of the Code of Va.

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.

*For Subdivision Streets and Alleys, radius width and angle should be in accordance with Subdivision Street Design Guide in the Road Design Manual, Appendix B.
Commercial Entrance Designs to Serve Drive-In Type Businesses

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board's "Policy for Integrating Bicycle and Pedestrian Accommodations".
Low Volume Commercial Entrance Design along Highways with Shoulders

LOW VOLUME COMMERCIAL ENTRANCE DESIGN
ALONG HIGHWAYS WITH SHOULDERS

Site Requirements For This Design
Maximum Highway VPD: 5,000
Maximum Entrance VPD: 200
Maximum Entrance VPD
Truck Trips: 10%

SINGLE TWO - WAY ENTRANCE

Letter Symbol Dimensions
C 25’ Minimum
U* 28’ Minimum, Curb and Gutter
W* 18’ Minimum
Y* 90° Preferred

Notes:
Entrance details shown on this sheet may be modified to meet specific site requirements as directed or approved by the Engineer at the Residency or District, when based on sound engineering principles.

FIGURE 4-15 LOW VOLUME COMMERCIAL ENTRANCE DESIGN ALONG HIGHWAYS WITH SHOULDERS

Note: All entrance design and construction shall accommodate pedestrian and bicycle users of the highway in accordance with the Commonwealth Transportation Board’s “Policy for Integrating Bicycle and Pedestrian Accommodations”.

* For Subdivision Streets and Alleys, radii, width and angle should be in accordance with Subdivision Street Design Guide in the Road Design Manual, Appendix B.
